ALEXANDER RADCHENKO & GRAHAM W. ELMES

MYRMICA EMERYI, A NEW ANT SPECIES FROM SOUTH-EAST ASIA
(HYMENOPTERA, FORMICIDAE)

In 2007, one of us (AR) found four workers, labelled as Myrmica ritaë Emery, in the collection of Carlo Emery (Museo Civico di Storia Naturale “Giacomo Doria” in Genoa, Italy, MSNG). Although these specimens were most probably identified by Emery himself, they in fact, are not M. ritaë but belong to a new species from the ritaë species-group. We describe them below as M. emeryi.

Original photos of the holotype of M. emeryi were made using a Leica MZ16 microscope with attached camera IC3D and the computer program Leica Application Suite. Measurements of specimens (accurate to 0.01 mm) were taken and these were used to calculate various indices.

Morphometrics:

| HL | maximum length of head in dorsal view, measured in a straight line from the most anterior point of clypeus (including any carina or ruga, when they protrude beyond the anterior margin) to the mid-point of occipital margin. |

---

** Centre for Ecology and Hydrology Wallingford, Crowmarsh Gifford, Wallingford, Oxfordshire, OX10 8BB, United Kingdom; e-mail: gwe@ceh.ac.uk
HW maximum width of head in dorsal view behind (above) the eyes.
FW minimum width of frons between the frontal carinae.
FLW maximum distance between the outer borders of the frontal lobes.
SL maximum straight-line length of scape from its apex to the articulation with condylar bulb.
AL diagonal length of the alitrunk (seen in profile) from anterior end of the neck shield to the posterior margin of propodeal lobes (workers) and from the most anterodorsal point of alitrunk to posterior margin of propodeal lobes (queens and males).
HTL maximum length of hind tibia, measured from the junction with femur to the junction with the first tarsal joint.
PNW maximum width of pronotum in dorsal view (workers).
PL maximum length of petiole in dorsal view, measured from the posterodorsal margin of petiole to the articulation with propodeum; the petiole should be positioned so that measured points lay on the same plane.
PW maximum width of petiole in dorsal view.
PH maximum height of petiole in profile, measured from the uppermost point of the petiolar node perpendicularly to the imaginary line between the anteroventral (just behind the subpetiolar process) and posteroventral points of petiole.
PPL maximum length of postpetiole in dorsal view between its visible anterior and posterior margins.
PPW maximum width of postpetiole in dorsal view.
PPH maximum height of postpetiole in profile from the uppermost to lowermost point, measured perpendicularly to the tergo-ster nal suture.
ESL maximum length of propodeal spine in profile, measured along the spine from its tip to the deepest point of the propodeal constriction at the base of the spine.
ESD distance between the tips of propodeal spine in dorsal view.
SCW maximum width of scutum in dorsal view (queens and males).
SCL length of scutum+scutellum in dorsal view (queens and males).
AH height of alitrunk, measured from upper level of mesonotum perpendicularly to the level of lower margin of mesopleuron (queens and males).

*Myrmica emeryi* n. sp.

**Material examined.** Holotype worker, "Pulo Laut" (middle specimen on the pin with 3 workers) (MSNG); paratypes: 2 workers, on the pin with holotype; 1 worker, "Pulo Laut" (MSNG).

Workers (Figs 1-5).

Head distinctly longer than wide, with convex sides and occipital margin, and broadly rounded occipital corners. Upper latero-ventral corners of head pointed. Anterior clypeal margin feebly convex and notched medially. Mandibles with 8-9 teeth. Frontal carinae feebly curved, frons wide, frontal lobes somewhat raised vertically. Antennal sockets not surrounded by rugulae. Scape long, distinctly longer than head-length, gradually curved at the base, without any trace of lobe or carina.

Alitrunk long and low, with somewhat flattened mesonotal dorsum, promesonotal suture dorsally indistinct. Metanotal groove distinct, rather deep. Propodeal lobes projecting apically to form sharp teeth. Propodeal spines very long, slightly widened at the base, sharp, straight, inclined at less than 45° in profile and divergent (seen from above). Petiole long, more than twice longer than high, its anterior surface concave, dorsum of node almost flat; postpetiole fig-shaped in dorsal view, slightly higher than long. Spurs on middle and hind tibiae well developed and pectinate.

Frons between frontal carinae level with the eyes with only four coarse longitudinal rugae. Lateral parts of head dorsum with coarse, slightly sinuous longitudinal rugae, occiput and temples with coarse reticulation. Clypeus finely longitudinally rugose, mandibles longitudinally rugulose. Surface of head dorsum between rugae smooth and shiny.

Alitrunk dorsum with coarse reticulation, sides with coarse longitudinal, partly sinuous rugae, surface between rugae smooth and shiny. Petiolar node with longitudinal rugae, postpetiole with longitudinally-concentric rugosity, surface of waist appears shiny, but very finely, superficially micropunctate. Gaster smooth and shiny.

Occipital margin of head with numerous erect to suberect hairs, lateral margins with a few similar hairs, alitrunk dorsum and waist with more abundant and longer hairs. Scape and tibiae with subdecumbent pilosity. Alitrunk and gaster dark reddish-brown, head dorsum and gaster somewhat lighter, appendages yellowish-red.

Queens, males and ecology are unknown.

**Etymology.** The species is dedicated to Prof. Carlo Emery, the famous Italian myrmecologist.

**Comparative diagnosis.** *M. emeryi* clearly belongs to the *ritae*-complex of the *ritae* species-group (see Radchenko & Elmes 1998, 2001 a, 2001 b; Radchenko *et al.* 2001, 2006) and given the paucity of material until relatively recently, its misidentification as *M. rita* is not so surprising. *M. emeryi* most resembles *M. margaritae* Emery, *M. formosae* Wheeler, and *M. sinensis* Radchenko, Zhou & Elmes, which are characterised by a very coarse rugosity of the head (frons between frontal carinae level with the eyes with only four coarse longitudinal rugae). The abundant long standing hairs on the alitrunk dorsum and occipital margin of the head well differentiates it from *M. margaritae*, which has only a few standing hairs on these areas. On the other hand, it differs from *M. formosae* and *M. sinensis* by the much less abundant standing hairs on the lateral margins of the head (less that five versus more than 20). Additionally, *M. formosae*, unlike *M. emeryi*, has no reticulation.
on the head dorsum and alitrunk dorsum. The absence of reticulation on the petiolar and postpetiolar dorsum of *M. emeryi* clearly distinguishes it from *M. sinensis*, which has coarse reticulation on these surfaces.

**Notes.** Two pins with the holotype and paratype specimens have labels “Pulo Laut” (see Figs 6, 7), but no other collection information. We searched different geographic atlases and the Internet, and found several localities with the same or similar spelling. All of them are islands situated near Malaysia or Borneo (“pula” means “island” in Malaysian). If any of these localities is correct, then *M. emeryi* is the most geographically isolated and has the most southern distribution of all known *Myrmica* species.

Figs 6-7 - Photos of original labels of the type specimens of *Myrmica emeryi* (6 - holotype, 7 - paratype).

**ACKNOWLEDGEMENTS**

We are sincerely grateful to Dr. Fabio Penati and Dr. Roberto Poggi (Genoa, Italy) for the opportunity to check Emery’s collection. This work was supported by the grant of the Ministry of High Education and Science of Poland No. 2P04C 064 29 (AR), and funded as part of the basic science programs of our Institutions.

ABSTRACT

Myrmica emeryi, a new ant species belonging to the rita species-group, is described based on four workers, from Pulo Laut (between Malaysia and Borneo) preserved in the Museo Civico di Storia Naturale “Giacomo Doria”, Genoa, Italy. Its taxonomic position is discussed.

RIASSUNTO

Myrmica emeryi, una nuova specie di formica del Sud-est asiatico (Hymenoptera, Formicidae).
